

Installation Steps

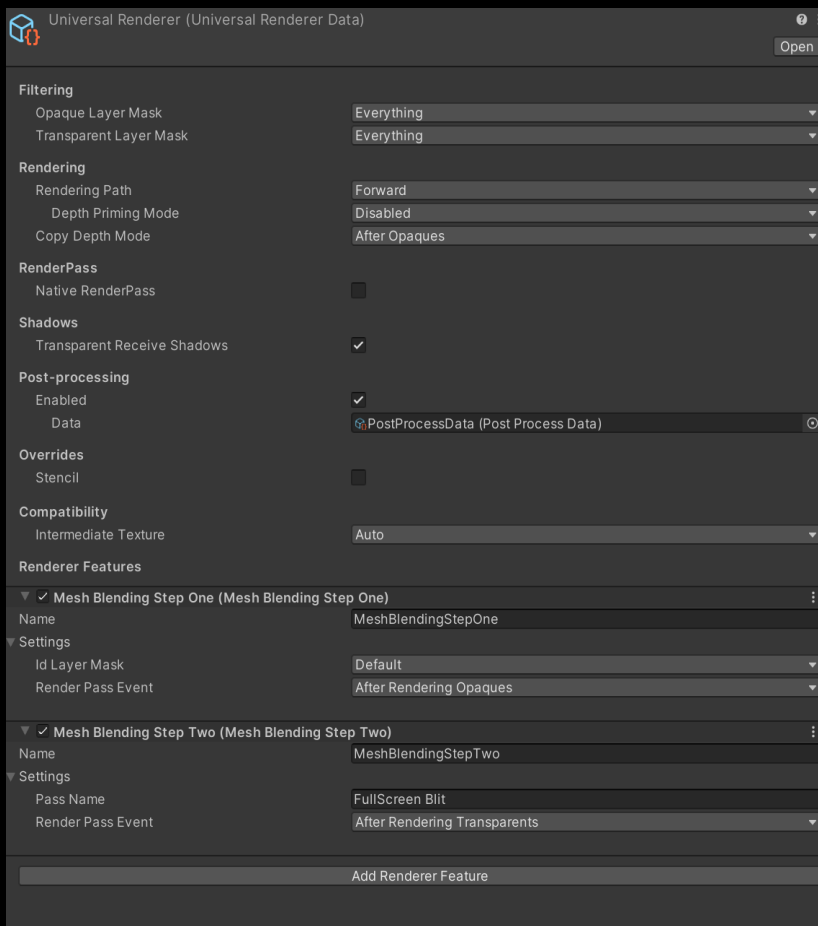

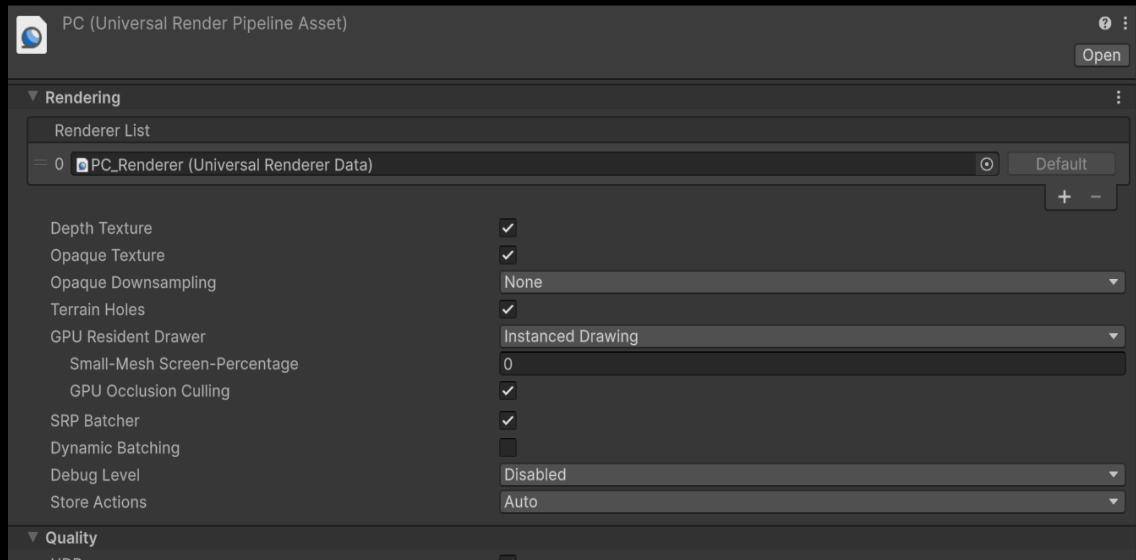

First go to your URP settings Render asset, usually located at Settings folder inside Assets or in the Project Settings -> Graphics->Scriptable Render Pipeline.

Enable Depth Texture

Enable Opaque Texture

Opaque Downsampling None // set it no None, because it can affect the quality of the final blending otherwise.

You can do whatever you want with the other settings those are the only we need.

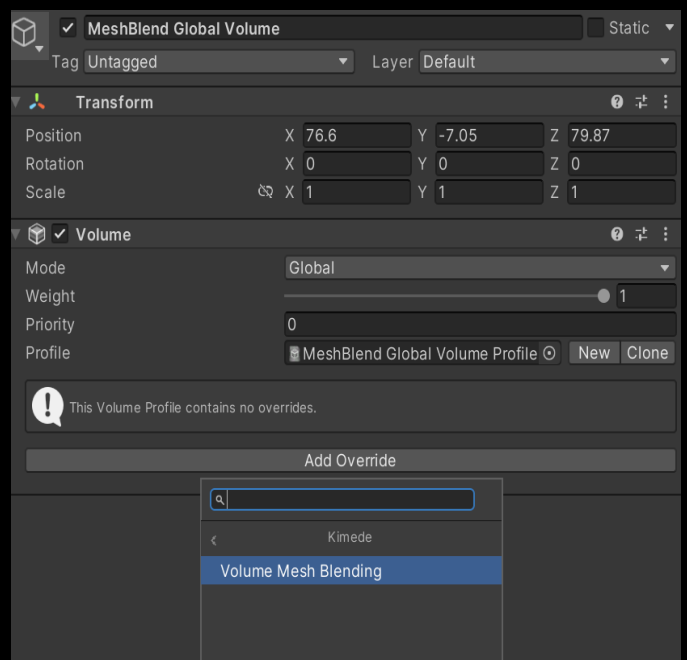

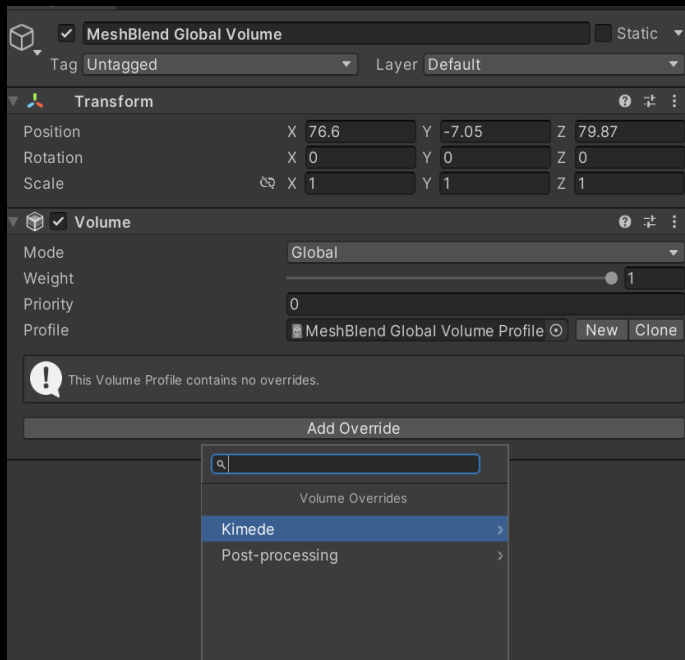

Locate the Render file of your URP asset and add those two to render passes, Mesh Blending Step One and set the Id Layer Mask field to a layer you want to be used for blending meshes, or just let it Default for now.

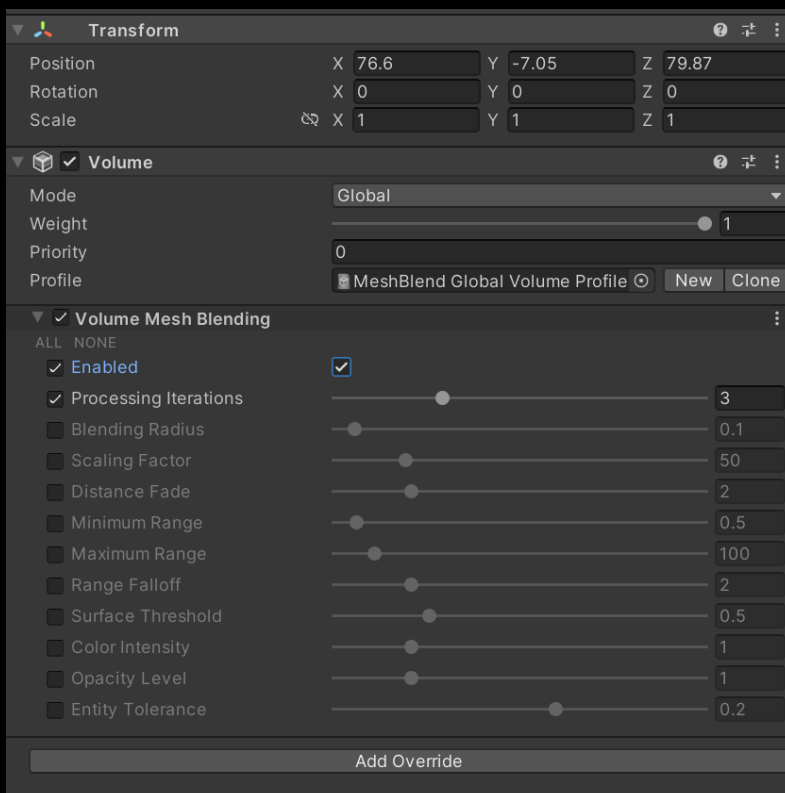

Also add the Mesh Blending Step Two, the default should look like this picture.

How to use it?

It's pretty easy, just add a Native Unity Global or Local Volume to a gameObject in a scene, add the Kimede->Volume Mesh Blending.

After toggle Enabled to make it work right away, and it should be working now if everything is set up correctly. It should work just like any unity native effect, you can use it local, global or mix them.

Warning : If you want to disable it temporarily you should Add Global Volume with Overriding Enable to False just like the picture, cause other local volumes with higher priority may enable it again and it will keep enabled until leaving the collision box and be disabled again. Just pay attention if your are using a local or global volume and their priority and you are safe.
